Planner: from the product's goal x = v, with l ≤ h ≤ u, and the module's primitives A, B and C, it builds three kinds of flow:

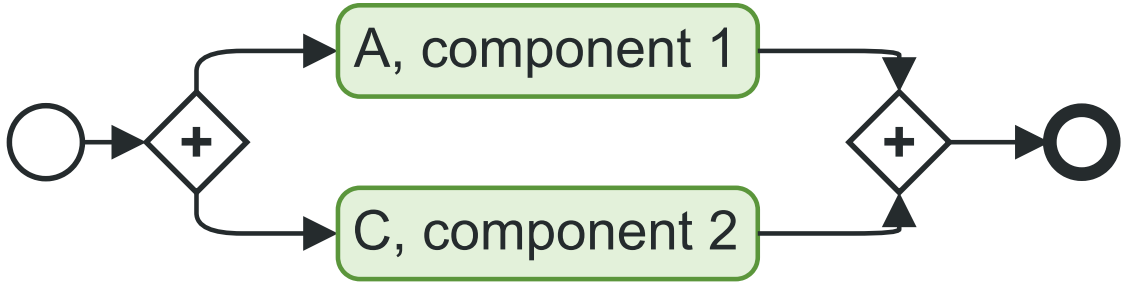

1 Sequence

B gives what A needs

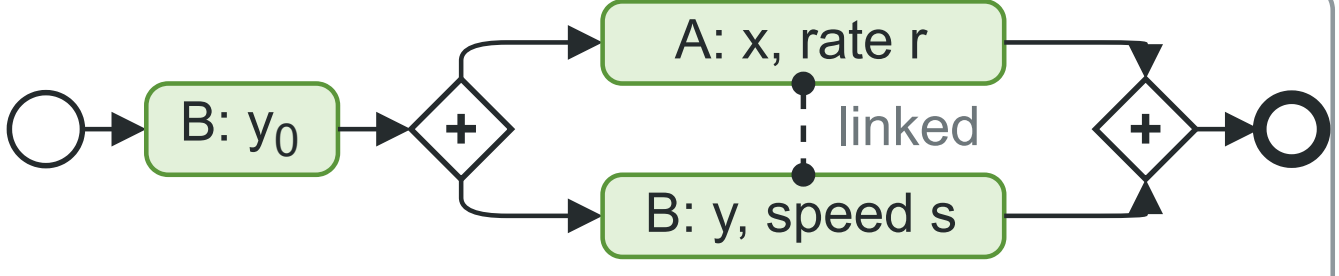

2 Parallel

the steps share no component or state

3 Coordinated steps

a bound links two changing states

r is set so that a·r + b·s = 0, which keeps h = a·x + b·y within [l, u] while both run
